# Lab - Introduction to Nmap

#### Overview

Network Mapper (Nmap) is a network scanning and host detection tool that is very useful during several steps of penetration testing. Nmap is not limited to merely gathering information and enumeration, but it is also a powerful utility that can be used as a vulnerability detector or a security scanner. Nmap is a multipurpose tool, and it can be run on many different operating systems including Windows, Linux, BSD, and Mac. Nmap can be used to:

- Detect any live hosts present on the network (host discovery)
- Detect any open ports on a host (port discovery or enumeration)
- Detect software and the of the respective port assigned to the service (service discovery)
- Detect the operating system, hardware address, and the software version
- Detect any vulnerabilities and security holes using Nmap scripts

Nmap is a very common tool, and it is available for both the command line interface and the graphical user interface. The objective of this lab is to create a guide containing information about Nmap and its usage.

- Introduction to Nmap
- Learn Nmap parameters and techniques of scanning
- Introduction to operating system detection
- Nmap tutorial

Nmap uses different techniques to perform scanning including TCP connect () scanning, TCP reverse ident scanning, FTP bounce scanning and so on. All these types of scanning have their advantages and disadvantages.

## Hardware Requirements for This Lab:

- One virtual install of Kali Linux
- One virtual install of a Window or Linux target machine.

## **Using Nmap Effectively**

The usage of Nmap depends on the target machine and the differences between simple (basic) scanning and advanced scanning. What follows are examples of some basic commands and their usage. In part II of this lab, the more advanced Nmap scanning techniques are shown.

In this example, we are scanning a single IP address of 192.168.225.138. You can discover the IP address of your host machine by typing IFCONFIG at the terminal prompt. This will show you your assigned IP address. You can then substitute the default IP address used in the lab with the IP address of your machine for scanning a single host.

```
root@kali:~

File Edit View Search Terminal Help

root@kali:~# ifconfig
eth0: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
    inet 192.168.225.138 netmask 255.255.255.0 broadcast 192.168.225.255
    inet6 fe80::20c:29ff:fe66:ccel prefixlen 64 scopeid 0x20<link>
    ether 00:0c:29:66:cc:el txqueuelen 1000 (Ethernet)
    RX packets 28 bytes 6431 (6.2 KiB)
    RX errors 0 dropped 0 overruns 0 frame 0
    TX packets 34 bytes 3503 (3.4 KiB)
    TX errors 0 dropped 0 overruns 0 carrier 0 collisions 0
```

## Answer the following questions:

- What is your IP address? In the above image, eth0 interface has been assigned the IP address of 192.168.225.138. This is my IP address; yours will differ!
- What is the network portion of your IP? (For any class C, it is the first three octets 192.168.225.x The x in the last octet represents the IP address assigned to the host. My Kali host was given 138 as it's host IP.)
- What is your subnet mask? My network is using a default class C network, so my subnet mask is 255.255.255.0. This reads to say the first three octets are all used up, the O (zero) in the last octet tells the network the entire 8 bits can be used to assign an IP to for up to 254 network devices.

To scan a single system use:

## # nmap 192.168.225.1

```
root@kali: ~
                                                                                                O 0 0
 File Edit View Search Terminal Help
       kali:~# nmap 192.168.225.1
Starting Nmap 7.12 ( https://nmap.org ) at 2016-08-24 07:46 EDT Nmap scan report for 192.168.225.1 Host is up (0.00027s latency). Not shown: 988 closed ports PORT STATE SERVICE

root@kali:~#
```

The first part of the lab covered the basics of Nmap scanning. The second part, we will learn more advanced scanning techniques.

## Part II

## **Nmap Scanning Techniques**

In this section, we will discuss the more popular scanning technique in detail.

## TCP SYN Scan (-sS)

It is a basic scan, and it is also called half-open scanning because this technique allows Nmap to get information from the remote host without the complete TCP handshake process, Nmap sends SYN packets to the destination, but it does not create any sessions. As a result, the target computer can't create any log of the interaction because no session was initiated, making this a feature of the TCP SYN scan.

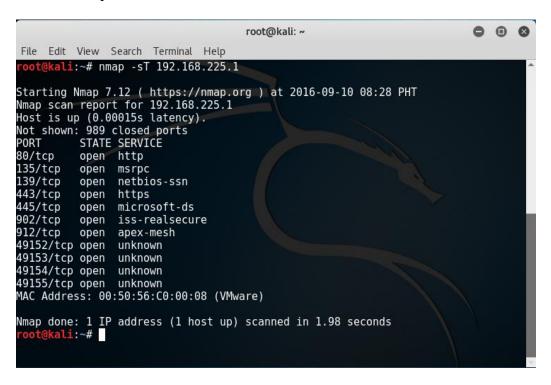

If there is no scan type mentioned on the command, then a TCP SYN scan is used by default, but it requires the root/administrator privileged.

# nmap -sS 192.168.225.1 (Replace the IP with that of a target machine running on your virtual network)

```
root@kali: ~
 File Edit View Search Terminal Help
    t@kali:~# nmap -sS 192.168.225.1

49155/tcp open unknown
MAC Address: 00:50:56:C0:00:08 (VMware)
Nmap done: 1 IP address (1 host up) scanned in 1.80 seconds
```

## TCP connect() scan (-sT)

This the default scanning technique used, if and only if the SYN scan is not an option because the SYN scan requires root privilege. Unlike the TCP SYN scan, it completes the normal TCP three-way handshake process and requires the system to call connect(), which is a part of the operating system. Keep in mind that this technique is only applicable to find out the TCP ports, not the UDP ports.

# nmap -sT 192.168.225.1

(Replace the IP with that of a target machine running on your virtual network)

```
root@kali: ~
                                                                               0 0

```

## UDP Scan (-sU)

This technique scans for open UDP port on the target machine. Since we are using UDP there is no three-way SYN handshake. But we can make the scanning more effective by using -sS along with -sU. UDP scans send the UDP packets to the target machine, and waits for a response—if an error message arrives saying the ICMP is unreachable, then it means that the port is closed; but if it gets an appropriate response, then it means that the port is open.

# nmap -sU 192.168.225.1 (Replace the IP with that of a target machine running on your virtual network)

```
O 0 0
                                         root@kali: ~

```

## FIN Scan (-sF)

Sometimes a normal TCP SYN scan is not the best solution because of the firewall. IDS and IPS filtering can block the SYN packets. A FIN scan sends the packet with only a FIN flag, so it is not required to complete the TCP handshaking.

# nmap -sF 192.168.225.1 (Replace the IP with that of a target machine running on your virtual network)

```
File Edit View Search Terminal Help

root@kali:~# nmap -sF 192.168.225.1

Host is up (0.000054s latency).

All 1000 scanned ports on 192.168.225.1 are closed

MAC Address: 00:50:56:C0:00:08 (VMware)

Nmap done: 1 IP address (1 host up) scanned in 1.79 seconds

root@kali:~#
```

The target computer will not be able to create a log of this scan (again, an advantage of FIN). Just like a FIN scan, we can perform a xmas scan (-sX) and Null scan (-sN). The idea is same, but there is a difference between each type of scan. For example, the FIN scan sends the packets containing only the FIN flag, whereas the Null scan does not send a bit on any ICMP packet. The xmas sends FIN, PSH, and URG flags.

## Ping Scan (-sP)

Ping scanning is unlike the other scan techniques because it is only used to find out whether the host is alive or not, it is not used to discover open ports. Ping scans require root access so ICMP packets can be sent, but if the user does not have administrator privilege, then the ping scan uses connect() call.

# # nmap -sP 192.168.225.1 (Replace the IP with that of a target machine running on your virtual network)

```
root@kali:~

Host is up (0.00012s latency).

MAC Address: 00:50:56:C0:00:08 (VMware)

Nmap done: 1 IP address (1 host up) scanned in 1.88 seconds

root@kali:~#
```

## **Version Detection (-sV)**

Version detection is the technique used to find out what software version is running on the target computer and on the respective ports. It is unlike the other scanning techniques because it is not used to detect the open ports, but it requires the information from open ports to detect the software version. In the first step of this scan technique, version detection uses the TCP SYN scan to find out which ports are open.

# nmap -sV 192.168.225.1 (Replace the IP with that of a target machine running on your virtual network)

```

## Idle Scan (-sI)

Idle scan is a favorite technique of most hackers. This is an advanced scan that provides complete anonymity while scanning. In the idle scan, Nmap doesn't send the packets from your real IP address—instead of generating the packets from the attacker machine, Nmap uses another host from the target network to send the packets. Let's consider an example to understand the concept of idle scan:

# nmap -sI 192.168.225.2 192.168.225.1 (Replace the IP with that of a target machine running on your virtual network)

```
File Edit View Search Terminal Help

root@kali:~# nmap -sI 192.168.225.2 192.168.225.1

WARNING: Many people use -Pn w/Idlescan to prevent pings from their true IP. On the other hand, timing info Nmap gains from pings can allow for faster, more re liable scans.

Starting Nmap 7.12 ( https://nmap.org ) at 2016-09-10 10:07 PHT Idle scan using zombie 192.168.225.2 (192.168.225.2:443); Class: Incremental Nmap scan report for 192.168.225.1
Host is up (0.00013s latency).
All 1000 scanned ports on 192.168.225.1 are closed|filtered MAC Address: 00:50:56:C0:00:08 (VMware)

Nmap done: 1 IP address (1 host up) scanned in 7.68 seconds

root@kali:~#
```

The idle scan technique (as mentioned above) is used to discover the open ports on 192.168.225.1 while it uses the zombie\_host (192.168.225.2) to communicate with the target host. So, this is an ideal technique to scan a target computer anonymously.

There are many other scanning techniques are available like FTP bounce, fragmentation scan, IP protocol scan and so on; but in this lab, you learned some of the more popular scanning techniques.

In this next section, we will learn Nmap's operating system (OS) detection and discovery techniques.

### **OS Detection**

One of the most important features that Nmap has is the ability to detect remote operating systems and software. It is very helpful during a penetration test to know about the operating system and the software used by the remote computer because you can easily predict the known vulnerabilities from this information.

Nmap has a database called *nmap-os-db*, the database contains information on more than 2,600 operating systems. Nmap sends TCP and UDP packets to the target machine and then it examines the response by comparing the result with the database. The Nmap operating system

discovery technique is slightly slower than the scanning techniques because OS detection involves the process of finding open ports.

The example above clearly demonstrates that the Nmap first discovers the open ports, then it sends the packets to discover the remote operating system. The OS detection parameter is -O (capital O).

# nmap -O 192.168.225.1 (Replace the IP with that of a target machine running on your virtual network)

```

Your results will differ from those in the preceding image. This is only an example of what you might see.

Nmap OS fingerprinting technique discovers the:

- Device type (router, workstation, and so on)
- Running (running operating system)
- OS details (the name and the version of OS)
- Network distance (the distance in hops between the target and attacker)

Suppose the target machine has a firewall, IDS, and IPS all enabled. You can use the command - **PN** to ensure that you do not ping to find the remote operating system. The -PN tells Nmap not to ping the remote computer since sometimes firewalls block the request.

# nmap -O -PN 192.168.225.1/24 (Replace the IP with that of a target machine running on your virtual network)

```

Your results will differ from those in preceding image. This is only an example of what you might see.

The command assumes every host on the network is alive so there is no need to send a ping request as. We bypass the ping request and go straight to discovering the operating system.

The Nmap OS detection technique works on the basis of an open and closed port. If Nmap fails to discover the open and closed port, then it gives the error:

Warning: OSScan results may be unreliable because we could not find at least 1 open and 1 closed port

This is an undesirable situation, and it is good to limit the operating system scans if Nmap is not sure about the OS. If Nmap is not sure about the OS, then there is no need to detect by using – osscan\_limit.

If it is difficult for Nmap to detect the remote OS accurately, you have the option of using Nmap's guess feature: *-osscan-guess* finds the nearest match of the target operating system.

# nmap -O --oss can-guess 192.168.225.1/24 (Replace the IP with that of a target machine running on your virtual network)

## **Summary**

Sometimes the best way to understand something is to see it in action. This lab included examples of Nmap used in most typical circumstances. Those new to Nmap should not expect to understand everything at once. This lab was a broad overview of Nmap.

As hackers, pentesters, security auditors or network administrators, we learn to have a number of favorite Nmap commands we keep stored in our brain housing group. I have three or four favorites which cover roughly 99% of every discovery scan I need to perform. The trick with working in technology is really simple, you don't have to know all the answers, but you are expected to know how to find the answers.

End of the lab!
